Introduction

The purpose of this assignment was to develop a Bluetooth-controlled system using an Arduino microcontroller, a relay module, and a mobile application built using MIT App Inventor. The objective was to wirelessly control an LED via a relay, demonstrating the principles of embedded systems and wireless communication. This project combines hardware and software elements to achieve seamless interaction between the physical and digital worlds.

Function

- Establish Bluetooth communication between Arduino and a mobile app.
- Control a relay to switch an LED ON and OFF.
- Create a mobile app with buttons to send commands (ON and OFF) using MIT App Inventor.
- Display Bluetooth connection status in the app.
- Implement Arduino code to process Bluetooth commands and operate the relay.

Pin Connections:

- Bluetooth Module:
 - \circ VCC \rightarrow Arduino 5V
 - \circ GND \rightarrow Arduino GND
 - \circ TX \rightarrow Arduino RX (Pin 0)
 - \circ RX \rightarrow Arduino TX (Pin 1)

• Relay Module:

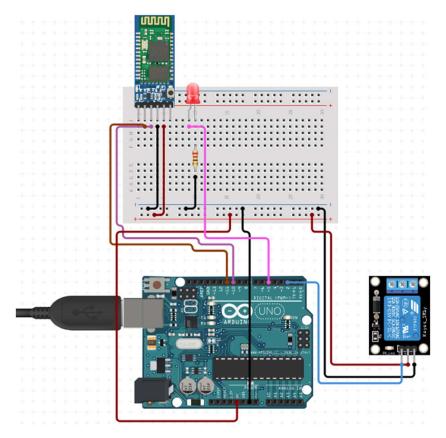

- \circ VCC \rightarrow Arduino 5V
- \circ GND \rightarrow Arduino GND
- \circ IN → Arduino Pin 8
- Relay COM → Arduino 5V.

• LED Circuit:

- o Positive leg (longer) \rightarrow Relay NO (Normally Open) terminal.
- Negative leg (shorter) \rightarrow 220 Ω resistor \rightarrow Arduino GND

This setup allows the Arduino to control the relay, which in turn controls the LED.

Circuit Diagram

Algorithms and Logic

The Arduino sketch was designed to:

1. **Initialize the Serial Communication** for Bluetooth communication:

NOTE:

Ensuring RX/TX connections were disconnected during code uploads was critical to avoid conflicts.

2. Control the Relay:

Commands received via Bluetooth ('1' or '0') activate or deactivate the relay.

3. Ensure Logic Compatibility:

The relay operates with active-low logic, so the LOW signal turns it ON, and HIGH turns it OFF.

Code:

```
char receivedCommand; // To store the command received via
Bluetooth
int relayPin = 8;  // Pin connected to the relay IN terminal
void setup() {
 pinMode(relayPin, OUTPUT); // Set relay pin as output
 digitalWrite(relayPin, LOW); // Ensure relay starts in OFF
state
  Serial.begin(9600); // Initialize serial communication for
Bluetooth
  Serial.println("Ready to receive commands via Bluetooth!");
}
void loop() {
  // Check if data is available on the Bluetooth connection
  if (Serial.available() > 0) {
    receivedCommand = Serial.read(); // Read the incoming
command
    if (receivedCommand == '0') {
      digitalWrite(relayPin, HIGH); // Turn ON the relay
      Serial.println("Relay ON (LED ON)"); }
    else if (receivedCommand == '1') {
      digitalWrite(relayPin, LOW); // Turn OFF the relay
      Serial.println("Relay OFF (LED OFF)");
    } } }
```

Application Development

To create the mobile application, we used **MIT App Inventor**. The app provides an interface for selecting the Bluetooth module and sending commands ("1" and "0") to control the LED.

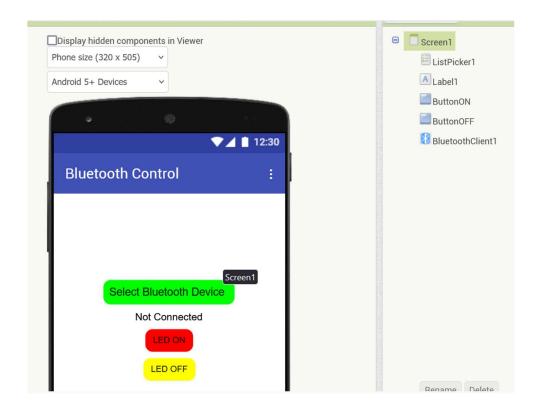

Steps to Develop the App:

1. Creating the App on a Mobile Device:

- We accessed MIT App Inventor from a laptop to design the application.
- The MIT AI2 Companion app was installed on the mobile device to test the app in real-time.
- The app was linked to the phone by scanning the QR code provided by MIT App Inventor.

2. User Interface Design:

- o Added a ListPicker to display and select Bluetooth devices.
- o Added two **Buttons** (LED ON and LED OFF) for control.
- o Added a Label to display the connection status.
- o Included a **BluetoothClient** component to handle communication.

3. Block Logic

```
when ListPicker1 .BeforePicking
   set ListPicker1 •
                     Elements *
                                 to (
                                      BluetoothClient1 *
                                                        AddressesAndNames *
when ListPicker1 .AfterPicking
           call BluetoothClient1 .Connect
                                             ListPicker1 *
                                                          Selection *
                                   address
          🧔 if
                 BluetoothClient1 IsConnected
          then set Label1 . Text to
                                                      Connected to
                                                    ListPicker1 *
                                                                  Selection *
                set Label1 . Text to
                                          " Connection Failed "
when ButtonON .Click
   call BluetoothClient1 SendText
                              text
when ButtonOFF .Click
do call BluetoothClient1 .SendText
                              text
                                    " 0 "
```
